Abstract

We consider the spherically symmetric, asymptotically flat Einstein-Vlasov system. We find explicit conditions on the initial data, with ADM mass $M$, such that the resulting spacetime has the following properties: there is a family of radially outgoing null geodesics where the area radius $r$ along each geodesic is bounded by $2M$, the time-like lines $r = c \in [0, 2M]$ are incomplete, and for $r > 2M$ the metric converges asymptotically to the Schwarzschild metric with mass $M$. The initial data that we construct guarantee the formation of a black hole in the evolution. We also give examples of such initial data with the additional property that the solutions exist for all $r \geq 0$ and all Schwarzschild time, i.e., we obtain global existence in Schwarzschild coordinates in situations where the initial data are not small. Some
of our results are also established for the Einstein equations coupled
to a general matter model characterized by conditions on the matter
quantities.

1 Introduction

One of the many striking predictions of General Relativity is the assertion
that under appropriate conditions astrophysical objects like stars or galaxies
undergo a gravitational collapse resulting in a spacetime singularity. This
was first proven by Oppenheimer and Snyder [19] who constructed a semi-
explicit example of a homogeneous spherically symmetric ball of dust, i.e.,
of a pressure-less fluid, which under its self-consistent, general relativistic
gravitational interaction collapses. During this collapse the scalar curvature
of spacetime blows up at the centre of symmetry, and the geometry of space-
time breaks down there. This is referred to as the formation of a spacetime
singularity. An important feature of the Oppenheimer-Snyder solution is
that during the collapse a two-dimensional spacelike sphere evolves which
encloses the singularity and through which no causal curve, i.e., no light
ray or particle trajectory, can pass outward. In this way the spacetime sin-
gularity is isolated from the outside part of spacetime by a so-called event
horizon, and the singularity cannot be seen or in any other way be experi-
enced by observers outside the event horizon. This configuration was later
termed a black hole.

In the 1960s Penrose [20] proved that the formation of spacetime singu-
larities from regular initial data is not restricted to spherically symmetric,
especially constructed or isolated examples but is a genuine, stable feature
of spacetimes. However, this result gives little information about the geo-
metric structure of a spacetime with such a singularity. In particular, it is
in general not known if every spacetime singularity which arises from the
gravitational collapse of regular initial data is covered by an event horizon.
Since the existence of so-called naked singularities (for which, by definition,
the latter is not true) would violate predictability (it would not be possible
to predict from the initial data what an observer would see if he could ob-
serve a singularity), the cosmic censorship conjecture was formulated which
demands that any singularity which arises from the gravitational collapse of
generic regular initial data is indeed hidden behind an event horizon. The
restriction to generic data means that naked singularities are allowed to oc-
cur for a “null set” of the initial data. An important example where naked
singularities do form for a null set, but for which cosmic censorship holds
true, is the spherically symmetric Einstein-scalar field system, cf. [10, 11]. Actually the above is an informal statement of the so-called weak cosmic censorship conjecture [34, 12.1]; we will not be concerned with the strong version in the present paper. For a mathematical discussion and the definition of the weak cosmic censorship conjecture we refer to [12].

To deal with this conjecture in full generality is out of reach of the present level of mathematics, but under the assumption of spherical symmetry progress has been made in recent years. One important outcome of these investigations is that the answer is sensitive to which model is chosen to describe the matter. Christodoulou [7] showed that for dust, i.e., the matter model used by Oppenheimer and Snyder, cosmic censorship is violated. On the other hand, in a series of papers Christodoulou investigated a massless scalar field as matter model and showed in 1999 that weak and strong cosmic censorship hold true for this matter model; see [11] and the references therein.

In the present investigation the main example considered as a matter model is the so-called collisionless gas as described by the Vlasov equation. It is used extensively in astrophysics, cf. [6], to describe galaxies or globular clusters which are viewed as large ensembles of mass points which interact only through the gravitational field that the ensemble creates collectively. In a relativistic context this leads to the Einstein-Vlasov system. All results available for this system support the following

**Conjecture:** *Weak cosmic censorship holds for the Einstein-Vlasov system.*

We mention explicitly that, in contrast to dust, small, spherically symmetric initial data launch global solutions, i.e., the solutions are geodesically complete and hence satisfy cosmic censorship, cf. [25]. Also, the numerical simulations [5, 18, 29] which treat large initial data support the hypothesis that naked singularities do not form in the evolution. We point out a further interesting feature of Vlasov matter observed in these numerical studies: In a one-parameter family of solutions which for large parameters, i.e., large amplitudes of the initial data, collapse to a black hole the smallest black hole always has a strictly positive ADM mass, i.e., there is a mass gap. For some other models, e.g. a scalar field, the mass of the black hole as a function of the parameter is continuous and arbitrarily small black holes can form, cf. [15] for a review.

The aim of the present paper is to find explicit conditions on the initial data which ensure the formation of black holes. This class of initial data has the important property that, except for “boundary cases”, properly restricted small perturbations of the data lead to solutions with the same
properties. In this sense the established behaviour of the solutions is stable and not restricted to especially constructed solutions or initial data, respectively. It turns out that some of our results can be formulated for a general matter model which satisfies certain specific assumptions, and in order to give a broader impact to our results we shall do so. At the same time we emphasize that the Vlasov matter model is the only one which is presently known to actually satisfy all the assumptions needed for our arguments to go through.

As an interesting corollary to our main result we show that it is in fact possible to choose initial data for the Einstein-Vlasov system, which lead to formation of black holes, such that the solutions exist for all Schwarzschild time and all \( r \geq 0 \). We thus obtain global existence in Schwarzschild coordinates for initial data which are not small, and to the best of our knowledge this is the first global existence result in Schwarzschild coordinates for initial data which lead to gravitational collapse and formation of black holes.

One aspect of our result is that there is a set of initial data which leads to gravitational collapse such that weak cosmic censorship holds. This point should be related to an earlier result by Rendall [32], where it is shown that there exist initial data for the spherically symmetric Einstein-Vlasov system such that a trapped surface forms in the evolution. The occurrence of a trapped surface signals the formation of an event horizon. Indeed, Dafermos [13] has proved that if a spherically symmetric spacetime contains a trapped surface and the matter model satisfies certain hypotheses then weak cosmic censorship holds true. In [14] it was then shown that Vlasov matter does satisfy the required hypotheses. Hence, by combining these results it follows that initial data exist which lead to gravitational collapse and for which weak cosmic censorship holds. However, the proof in [32] rests on a continuity argument, and it is not possible to tell whether or not a given initial data set will give rise to a black hole. This is in contrast to the explicit conditions on the initial data, together with the detailed asymptotic structure, that we obtain in the present work. In this regard it is natural to relate our results to those of Christodoulou on the spherically symmetric Einstein-scalar field system [8] and [9]. In [8] it is shown that if the final Bondi mass \( M \) is different from zero, the region exterior to the sphere \( r = 2M \) tends to the Schwarzschild metric with mass \( M \). In Theorem 2.4 below we show that solutions of the spherically Einstein-Vlasov system, under certain conditions on the initial data, also converge to the Schwarzschild metric asymptotically. Furthermore, in [9] explicit conditions on the initial data are specified which guarantee the formation of trapped surfaces. This paper played a crucial role in Christodoulou’s proof [11] of the weak and strong cosmic censorship
conjectures mentioned above. The conditions on the initial data in [9] allow the ratio of the Hawking mass and the area radius to cover the full range, i.e., $2m/r \in (0, 1)$, whereas our conditions always require $2m/r$ to be quite close to one. However, we believe that to understand gravitational collapse in the case of Vlasov matter the essential situation is when $2m/r$ is large. We thus hope that the results in the present paper will lead to progress on the general understanding of gravitational collapse and the weak cosmic censorship conjecture in the case of Vlasov matter.

The Vlasov matter model has a further property to recommend it when compared to other matter models. For the Vlasov-Poisson system, which arises as the Newtonian limit of the Einstein-Vlasov system in a rigorous sense [26, 31], and which is used extensively in astrophysics, there is a global existence and uniqueness result for general, smooth initial data [17, 21]. This means in particular that any breakdown of a solution of the Einstein-Vlasov system can be expected to be a genuine, general relativistic effect such as a spacetime singularity and not only remainder of some bad behaviour which the matter model exhibits already on the Newtonian level.

To be more specific, consider now a smooth spacetime manifold $M$ equipped with a spacetime metric $g_{\alpha\beta}$; Greek indices run from 0 to 3. Then the Einstein equations read

$$G_{\alpha\beta} = 8\pi T_{\alpha\beta},$$

(1.1)

where $G_{\alpha\beta}$ is the Einstein tensor, a non-linear second order differential expression in the metric $g_{\alpha\beta}$, and $T_{\alpha\beta}$ is the energy-momentum tensor given by the matter content (or other fields) of the spacetime. To obtain a closed system, the field equations (1.1) have to be supplemented by

the evolution equation(s) for the matter

(1.2)

and

the definition of $T_{\alpha\beta}$ in terms of the matter and the metric.

(1.3)

It is often possible to specify conditions on (1.2) and (1.3) under which one can establish geometric properties of a spacetime described by the Einstein-matter system (1.1), (1.2), (1.3). The Penrose singularity theorem mentioned above is of this nature, and part of our arguments will also be presented in this form.

However, in order to verify such general conditions, in particular with respect to the existence of local or global solutions to the corresponding
initial value problem, a specific matter model must be chosen, and in the present paper this is a collisionless gas. All the particles in the gas are assumed to have the same rest mass, normalized to unity, and to move forward in time. Hence, their number density $f$ is a non-negative function supported on the mass shell

$$PM := \left\{ g_{\alpha\beta} p^\alpha p^\beta = -1, \ p^0 > 0 \right\},$$

a submanifold of the tangent bundle $TM$ of the spacetime manifold $M$; $p^\alpha$ are the canonical momenta corresponding to general coordinates $x^\alpha = (t, x^a)$ on $M$. We use coordinates $(t, x^a)$ with zero shift, and Latin indices run from 1 to 3. On the mass shell $PM$ the variable $p^0$ becomes a function of the remaining variables $(t, x^a, p^b)$:

$$p^0 = \sqrt{-g^{00}} \sqrt{1 + g_{ab} p^a p^b}.$$

The number density $f = f(t, x^a, p^b)$ satisfies a continuity equation, the so-called Vlasov equation, which says that $f$ is constant along the geodesics of the spacetime metric,

$$\partial_t f + \frac{p^a}{p^0} \partial_{x^a} f - \frac{1}{p^0} \Gamma^0_{\beta\gamma} p^\beta p^\gamma \partial_{p^0} f = 0,$$  (1.4)

where $\Gamma^0_{\beta\gamma}$ are the Christoffel symbols induced by the metric $g_{\alpha\beta}$. The energy-momentum tensor is given by

$$T_{\alpha\beta} = \int p_\alpha p_\beta f \frac{|g|^{1/2} dp^1 dp^2 dp^3}{-p^0},$$  (1.5)

where $|g|$ denotes the modulus of the determinant of the metric. The system (1.1), (1.4), (1.5) is the Einstein-Vlasov system in general coordinates. For an introduction to relativistic kinetic theory and the Einstein-Vlasov system we refer to [1] and [33].

If, for comparison, the matter is to be described as a perfect fluid with density $\rho$, four-velocity field $U^\alpha$, and pressure $P$, then the matter evolution equations are the Euler equations

$$U^\alpha \nabla_\alpha \rho + (\rho + P) \nabla^\alpha U_\alpha = 0,$$

$$(\rho + P) U^\alpha \nabla_\alpha U_\beta + (g_{\alpha\beta} + U_\alpha U_\beta) \nabla^\alpha P = 0,$$

where $\nabla_\alpha$ is the covariant derivative corresponding to the metric $g_{\alpha\beta}$. The energy-momentum tensor in this case is

$$T_{\alpha\beta} = \rho U_\alpha U_\beta + P (g_{\alpha\beta} + U_\alpha U_\beta).$$
To close the Einstein-Euler system it has to be supplemented by an equation of state $P = P(\mathcal{R})$. The choice $P = 0$ yields the dust matter model referred to above.

Due to the complexity of the field equations (1.1) very little can be said about the questions at hand for these equations in their general form. Since on the other hand these questions are of considerable interest also in spacetimes satisfying simplifying symmetry assumptions, we from now on focus on asymptotically flat, spherically symmetric spacetimes and write down the metric

$$ds^2 = -e^{2\mu(t,r)} dt^2 + e^{2\lambda(t,r)} dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\varphi^2)$$

in Schwarzschild coordinates. Here $t \in \mathbb{R}$ is the time coordinate, $r \in [0, \infty[$ is the area radius, i.e., $4\pi r^2$ is the area of the orbit of the symmetry group $SO(3)$ labeled by $r$, and the angles $\theta \in [0, \pi]$ and $\varphi \in [0, 2\pi]$ parameterize these orbits. Asymptotic flatness means that the metric quantities $\lambda$ and $\mu$ have to satisfy the boundary conditions

$$\lim_{r \to \infty} \lambda(t, r) = \lim_{r \to \infty} \mu(t, r) = 0. \quad (1.6)$$

For a metric of this form the 00, 11, and 01 components of the Einstein equations are found to be

$$e^{-2\lambda} \left(2r\lambda_r - 1\right) + 1 = 8\pi r^2 e^{-2\mu} T_{00}, \quad (1.7)$$

$$e^{-2\lambda} \left(2r\mu_r + 1\right) - 1 = 8\pi r^2 e^{-2\lambda} T_{11}, \quad (1.8)$$

$$\lambda_t = 4\pi r T_{01}, \quad (1.9)$$

where subscripts indicate partial derivatives. The 22 and 33 components are also nontrivial, but they are not needed for our analysis, and the remaining components vanish identically due to the symmetry assumption.

Our aim is to find explicit conditions on the initial data such that the corresponding solutions of the spherically symmetric, asymptotically flat version of the system (1.1), (1.2), (1.3) have the following property: There is an outgoing radial null geodesic $\gamma^+$ originating from $r = r_0 > 0$, i.e.,

$$\frac{d\gamma^+}{ds}(s) = e^{(\mu - \lambda)(s, \gamma^+(s))}, \quad \gamma^+(0) = r_0, \quad (1.10)$$

such that the solution exists on the outer region

$$D := \{(t, r) \in [0, \infty[^2 \mid r \geq \gamma^+(t)\}, \quad (1.11)$$
and \( \gamma^+ \) has the property that
\[
\lim_{s \to \infty} \gamma^+(s) < \infty.
\] (1.12)

This indicates that the matter distribution undergoes a gravitational collapse, and a black hole forms. In the case of Vlasov matter we obtain a more detailed picture which supports this interpretation: There exists an extremal, radially outgoing null geodesic \( \gamma^* \) in the outer domain \( D \) such that \( \lim_{s \to \infty} \gamma^*(s) = 2M \) where \( M \) is the ADM mass of the solution, and as \( t \to \infty \) the metric converges for \( r > 2M \) to the Schwarzschild metric representing a black hole of mass \( M \).

In the next section we state our main results for the Einstein-Vlasov system, where we specify classes of spherically symmetric initial data which lead to solutions showing the above behaviour. The Vlasov equation and the corresponding energy-momentum tensor components in the case of spherical symmetry are stated there. In Section 3 we give a general formulation of one of our results where no particular matter model is considered. The reason for this is that most steps in the proof of Theorem 2.2 below are of a general character and—besides the fact that for the Einstein-Vlasov system there is an existence theory for the initial value problem which guarantees the existence of solutions on \( D \)—the specific properties of Vlasov matter are used only in one key lemma. Hence it is natural to precisely single out the required conditions on the level of the macroscopic matter quantities. This clarifies the main mechanism in our method, and it may lead to applications of our method to other matter models. Using an additional feature of Vlasov matter we construct an alternative, and in some respects larger, class of initial data which ensure the formation of black holes, cf. Theorem 2.1.

The proofs of our results then proceed as follows. After stating some general auxiliary results in Section 4 we prove Theorem 3.1, which is the general-matter version of Theorem 2.2, in Section 5. The latter result is then established in Section 6 by showing that Vlasov matter satisfies the required general conditions on the matter for a suitable class of initial data. Theorem 2.1 is established in Section 7 together with Corollary 2.3 on global existence in Schwarzschild coordinates. For all these results it is essential to make sure that in the outer region \( D \) all the matter moves inward. In the case of general matter this is a condition which we have to impose on the solution, whereas in the case of Vlasov matter we can specify conditions on the initial data such that this is true. In Section 8 we prove the convergence of our solution to a Schwarzschild black hole of the corresponding ADM mass in the case of Vlasov matter.
2 Main results for Vlasov matter

In this section Eqns. (1.6)–(1.9) will be supplemented by the spherically symmetric version of the Vlasov equation together with expressions for the relevant components of the energy-momentum tensor so that a closed system is obtained, known as the spherically symmetric, asymptotically flat Einstein-Vlasov system.

In order to exploit the symmetry it is useful to introduce non-canonical variables on momentum space and write $f = f(t, r, w, L)$. For a detailed derivation of the corresponding equations we refer to [24]; here we just state the result. The Vlasov equation is

$$\partial_t f + e^{\mu - \lambda} \frac{w}{E} \partial_r f - \left( \lambda t w + e^{\mu - \lambda} \frac{L}{r^3 E} \right) \partial_w f = 0, \quad (2.1)$$

where

$$E = E(r, w, L) := \sqrt{1 + w^2 + L/r^2} = e^\mu p^0.$$ 

The variables $w \in (-\infty, \infty]$ and $L \in [0, \infty[$ can be thought of as the radial component of the momentum and the square of the angular momentum respectively. Notice that the latter is conserved along characteristics of the Vlasov equation. The matter quantities are given by

$$\rho(t, r) = e^{-2\mu} T_{00}(t, r) = \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_{0}^{\infty} E f(t, r, w, L) dL dw, \quad (2.2)$$

$$p(t, r) = e^{-2\lambda} T_{11}(t, r) = \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_{0}^{\infty} \frac{w^2}{E} f(t, r, w, L) dL dw, \quad (2.3)$$

$$j(t, r) = -e^{-(\lambda + \mu)} T_{01}(t, r) = \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_{0}^{\infty} w f(t, r, w, L) dL dw. \quad (2.4)$$

Notice that the quantities $\rho, p, j$ appear on the right hand sides of the field equations (1.7)–(1.9), and they are given in terms of $f$ alone, which is the main reason for using the non-canonical variables $w$ and $L$. The system (1.6)–(1.9), (2.1)–(2.4) is the spherically symmetric Einstein-Vlasov system in Schwarzschild coordinates. As initial data we need to prescribe an initial distribution function $\tilde{f} = \tilde{f}(r, w, L) \geq 0$, which should be compactly supported in $[0, \infty[ \times -\infty, \infty[ \times [0, \infty[$, and such that

$$\int_{0}^{r} 4\pi \eta^2 \tilde{\rho}(\eta) d\eta = 4\pi^2 \int_{0}^{r} \int_{-\infty}^{\infty} \int_{0}^{\infty} E \tilde{f}(\eta, w, L) dL dw d\eta < \frac{r}{2}. \quad (2.5)$$

The origin $r = 0$ is excluded from the support for technical reasons, but this could be avoided by using Cartesian coordinates. The condition (2.5) implies
that the equations (1.7) and (1.8) have solutions $\lambda$ and $\mu$, cf. Section 4, and since $\hat{f}$ has compact support, a property which is inherited by $f(t)$, the matter terms are well defined. If in addition $\hat{f}$ is $C^1$ we say that the initial data is regular. As is shown in [25] or [24], regular initial data launch a unique local solution for which all the derivatives which appear in the system exist classically. In Section 6 we discuss in more detail that this local solution extends to the whole outer region $D$ defined in (1.11).

To state our main results let $0 < r_0 < r_1$ be given, put $M = r_1/2$ (this is going to be the ADM mass of the solution), and fix $0 < M_{\text{out}} < M$ such that

$$\frac{2(M - M_{\text{out}})}{r_0} < \frac{8}{9}. \quad (2.6)$$

**Remark.** The value $8/9$ is chosen for definiteness, and any number less than one would do, effecting the values of some of the constants below.

Two different theorems will be stated below, corresponding to the following two situations.

(i) Let $R_1 > r_1$ be such that

$$R_1 - r_1 < \frac{r_1 - r_0}{6}, \quad (2.7)$$

or

(ii) let $R_1 > r_1$ be such that

$$\sqrt{\frac{R_1 - r_1}{R_1}} < \min \left\{ \frac{1}{6}, \frac{r_0^2}{12\kappa R_1 M}, \frac{r_1 - r_0}{8\kappa R_1} \right\}, \quad (2.8)$$

where the (explicit) constant $\kappa > 0$ will be specified in Theorems 2.2 and 3.1 below.

Finally, we define

$$R_0 := \frac{1}{2}(r_1 + R_1).$$

Denote by $\hat{\rho}$ the energy density induced by the initial distribution function $\hat{f}$. We require that all the matter in the outer region $[r_0, \infty]$ is initially located in the strip $[R_0, R_1]$, with $M_{\text{out}}$ being the corresponding fraction of the ADM mass $M$, i.e.,

$$\int_{r_0}^{\infty} 4\pi r^2 \hat{\rho}(r) dr = \int_{R_0}^{R_1} 4\pi r^2 \hat{\rho}(r) dr = M_{\text{out}}. \quad (2.9)$$
Furthermore, the remaining fraction $M - M_{\text{out}}$ should be initially located within the ball of area radius $r_0$, i.e.,

$$\int_0^{r_0} 4\pi r^2 \rho(r) dr = M - M_{\text{out}}. \quad (2.10)$$

**Remark.** The set up described above is quite similar to the set up in [9] for a scalar field. In [9] it is not required to have matter in an “inner” strip $[0, r_0]$, as is the case here in view of (2.10) and the condition $M_{\text{out}} < M$. The reason why we need some matter in the region $r \leq r_0$ is to ensure that initially ingoing matter continues to be ingoing for all times, cf. Lemma 6.1 below. If one only considers purely radially ingoing particles, i.e., with no angular momentum (which results in a non-smooth distribution function $f$), then we could allow for $M_{\text{out}} = M$. It is interesting to note that $p = \rho$ holds for Vlasov matter, if the particles have no angular momentum and their rest mass is zero, which is the case for the scalar field considered in [9].

Now we are in the position to formulate our main results for Vlasov matter. Corresponding to Case (i) above, we prove

**Theorem 2.1** Let $r_0, r_1, M$, and $M_{\text{out}}$ be given as above, and let $R_1$ satisfy (2.7). Then there exists a set $I_1$ of regular initial data for the spherically symmetric Einstein-Vlasov system such that if $\hat{f} \in I_1$, then (2.9) and (2.10) hold, the corresponding solution exists on $D$, and

$$\lim_{s \to \infty} \gamma^+(s) < \infty, \quad \lim_{s \to \infty} \int_{\gamma^+(s)}^{\infty} 4\pi r^2 \rho(s, r) dr > 0,$$

where $\gamma^+$ satisfies (1.10).

By abuse of notation we denote by $D$ both the outer region in spacetime defined by (1.11) and the part of the mass shell with $(t, r) \in D$.

The next theorem addresses Case (ii) above, assuming the stronger condition (2.8). This allows for a more straightforward proof, and the constraints on the momentum variables of the initial distribution function $\hat{f}$ which are used to specify the set $I_1$ will be slightly relaxed. Hence, the initial data set $I_1$ does not contain $I_2$ in Theorem 2.2 below, but it is larger in the sense that data in $I_2$ are quite close to containing a trapped surface, which is not necessarily the case for data in $I_1$. The precise form of $I_1$ and $I_2$ is specified in the proofs.

**Theorem 2.2** Let $r_0, r_1, M$, and $M_{\text{out}}$ be given as above and let $R_1$ satisfy (2.8) with $\kappa = 6$. Then there exists a set $I_2$ of regular initial data for the
spherically symmetric Einstein-Vlasov system such that if \( \hat{f} \in I_2 \), then (2.9) and (2.10) hold, the corresponding solution exists on \( D \), and

\[
\lim_{s \to \infty} \gamma^+(s) < \infty, \quad \lim_{s \to \infty} \int_{\gamma^+(s)}^\infty 4\pi r^2 \rho(s, r) \, dr > 0,
\]

where \( \gamma^+ \) satisfies (1.10).

The Einstein-Vlasov system has a wide variety of static, spherically symmetric solutions with finite ADM mass and finite radius, i.e., compact support of the matter, cf. [23, 27, 30]. Particularly interesting examples of initial data for which our results apply are obtained if the matter for \( r \leq r_0 \) is represented by such a static solution, more precisely:

**Corollary 2.3** Let \( f_s \) be a static solution of the spherically symmetric Einstein-Vlasov system with finite ADM mass \( M_s > 0 \) and finite radius \( r_s > 0 \). Define \( r_0 = r_s \), let \( r_1 > r_0 \) be arbitrary, \( M = r_1/2 \), and \( M_{\text{out}} = M - M_s \); the latter quantity is positive. Then the initial data sets \( I_1 \) and \( I_2 \) both contain data \( \hat{f} \) which coincide with the given static solution for \( 0 \leq r \leq r_0 \). The corresponding solution \( f \) of the Einstein-Vlasov system exists for all \( r \geq 0, \, t \geq 0 \) and coincides with the static solution \( f_s \) for all \( r \leq \gamma^+(t) \) and \( t \geq 0 \).

We prove this result at the end of Section 7. It represents a global existence result for the Einstein-Vlasov system in Schwarzschild time for data which are not small.

In the next section we formulate a version of Theorem 2.2 for quite general matter models. One reason for this is that the main mechanism behind our method becomes very transparent by posing sufficient conditions on the macroscopic matter terms rather than conditions on the initial distribution function \( \hat{f} \) as we did in the theorems above. Theorem 2.2 will then be a consequence of this generalization, cf. Section 6, whereas Theorem 2.1 is established in Section 7.

In these proofs it turns out that for the classes of initial data that we specify we can obtain somewhat sharper asymptotic information on \( \gamma^+ \) and the mass in the outer region; see (5.8) below. More importantly, we can establish the following additional information which shows that the solution evolves towards a Schwarzschild black hole of mass \( M \).

**Theorem 2.4** In the situation of Theorem 2.1 or Theorem 2.2 the following holds:
(a) There exist constants $\alpha, \beta > 0$ depending only on the initial data set $I_1$ or $I_2$ respectively such that if

$$ t \geq 0 \text{ and } r \geq 2M + \alpha e^{-\beta t} $$

then $f(t, r, \cdot, \cdot) = 0$, i.e., we have vacuum, and the metric equals the Schwarzschild metric

$$ ds^2 = -\left(1 - \frac{2M}{r}\right) dt^2 + \left(1 - \frac{2M}{r}\right)^{-1} dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\phi^2), $$

representing a black hole of mass $M$.

(b) For all $t \geq 0$ and $\gamma^+(t) \leq r \leq 2M + \alpha e^{-\beta t}$,

$$ \mu(t, r) \leq \ln \left(\frac{\alpha e^{-\beta t}}{2M + \alpha e^{-\beta t}}\right)^{1/2} $$

so that in the outer region $D$,

$$ \lim_{t \to \infty} \mu(t, r) = -\infty \text{ for } r \leq 2M, $$

and the timelike lines $r = c$, where $c \in [0, 2M]$, are incomplete and their proper lengths are uniformly bounded by a constant depending on $\alpha$, $\beta$ and $M$.

(c) Let

$$ r^* := \sup\{r \geq r_0 \mid \text{the radially outgoing null geodesic } \gamma \text{ with } \gamma(0) = r \text{ satisfies } \lim_{s \to \infty} \gamma(s) < \infty\}, $$

and let $\gamma^*$ be the radially outgoing null geodesic with $\gamma^*(0) = r^*$. Then

$$ \lim_{s \to \infty} \gamma^*(s) = 2M, $$

and every radially outgoing null geodesic $\gamma$ with $\gamma(0) > r^*$ is future complete with $\lim_{s \to \infty} \gamma(s) = \infty$.

3 The result for general matter models

In this section we specify the general assumptions on a matter model sufficient for our method to be applied. In order to keep the discussion consistent
with the Vlasov part of our arguments, and in view of the right hand sides of the field equations (1.7), (1.8), (1.9), it is convenient to use the notation

\[ \rho := e^{-2\mu}T_{00}, \quad p := e^{-2\lambda}T_{11}, \quad j := -e^{-\mu-\lambda}T_{01}. \]  

(3.1)

Firstly, we assume that the following two conditions are satisfied.

- The dominant energy condition holds. (DEC)
- The radial pressure \( p \) is non-negative. (NNP)

The dominant energy condition (DEC) plays a central role in general relativity and is the main criterion that a matter model should satisfy to be considered realistic. We refer to [16] for its definition. The non-negative pressure condition (NNP) is restrictive in the sense that it rules out, for example, a Maxwell field as matter model. However, for most astrophysical models it is a standard assumption, with e.g. fluid models satisfying this condition. For the purpose of this paper we only need to focus on two consequences of these two criteria, cf. [16] and [22]. The (DEC) condition implies, together with the (NNP) condition, that

\[ 0 \leq p \leq \rho \text{ and } |j| \leq \rho. \]  

(3.2)

Furthermore, by (DEC) any geodesic \((s, R(s))\) of a material particle or a light ray satisfies

\[ \left| \frac{dR(s)}{ds} \right| \leq e^{(\mu-\lambda)(s, R(s))}. \]  

(3.3)

The meaning of the latter condition is that locally the speed of energy flow is less than or equal to the speed of light.

Let \( \lambda, \mu, \rho, p, j \) correspond to a solution of the spherically symmetric Einstein-matter equations (1.6)–(1.9), (1.2), (1.3) in Schwarzschild coordinates, launched by initial data from a class \( I \). In order to investigate the global structure of the solutions it is necessary that they exist globally in an appropriate sense. In the situation at hand they need to exist on the outer region \( D \) defined in (1.11). In the spherical symmetric case the main obstruction for obtaining global solutions arises from the difficulties related to the centre of symmetry \( r = 0 \). For example, for a massless scalar field or a collisionless gas as matter model it has been shown that solutions remain regular away from \( r = 0 \) for general initial data, cf. [12, 2, 28]. On the other hand, for dust a singularity of shell crossing type can also occur at some \( r > 0 \). Although in that case there are no true geometric spacetime singularities, such behaviour has to be ruled out in order not to interfere
with the analysis of the solution on $D$. This can be achieved by proper assumptions on the initial data, cf. [7]. In view of (3.3) a possible break down of solutions at $r = 0$ will have no influence on the outer domain $D$. Hence we formulate a third condition, concerning global existence of solutions in the outer domain, as follows.

- For solutions launched by data from the set $I$, $\gamma^+$ defined by (1.10) exists on $[0, \infty]$, and $\lambda, \mu, \rho, p, j \in C^1(D)$. (GLO)

The three conditions above are of a quite general nature. The fourth and final condition however, is tightly connected to our method of proof.

- There exists a constant $c_1 > 0$ such that $\rho \leq -c_1 j$ in $D$. (GCC)

The acronym (GCC) stands for “gravitational collapse condition”, and this condition plays a crucial role for our method of proof. We emphasize that our main results show that for Vlasov matter there are initial data sets such that (GCC) holds. As a first consequence of (GCC) and (3.2), note that $j \leq 0$ in $D$, i.e., the matter is ingoing for all times. In this respect our present results complement [4], where purely outgoing matter is considered.

Let us now assume that our matter model satisfies (DEC) and (NNP), and that there exists an initial data set $I$ such that (GLO) and (GCC) hold as well. Then we have the following result, which should be viewed as a version of Theorem 2.2 for general matter.

**Theorem 3.1** Let $r_0, r_1, M, M_{out}$ be given as above and let $R_1$ satisfy (2.8) with $\kappa = 2c_1$. Assume that there exists an initial data set $I_3 \subset I$ such that (2.9) and (2.10) hold for all initial data in $I_3$. Then for any solution launched by initial data in $I_3$,

$$
\lim_{s \to \infty} \gamma^+(s) < \infty, \quad \lim_{s \to \infty} \int_{\gamma^+(s)}^{\infty} 4\pi r^2 \rho(s, r) \, dr > 0,
$$

where $\gamma^+$ satisfies (1.10).

The detailed information on the gravitational collapse which for Vlasov matter is provided in Theorem 2.4 is not available in the present situation, but the following still holds.

**Remark.** In the situation of Theorem 3.1,

$$
\lim_{t \to \infty} \mu(t, r) = -\infty \text{ for } \lim_{s \to \infty} \gamma^+(s) \leq r \leq r_1
$$
for some \( r_1 > \lim_{s \to \infty} \gamma^+(s) \). If \( r^* \) and \( \gamma^* \) are defined as in Theorem 2.4 then
\[
\lim_{s \to \infty} \gamma^*(s) < \infty,
\]
and every radially outgoing null geodesic \( \gamma \) with \( \gamma(0) > r^* \) is future complete with \( \lim_{s \to \infty} \gamma(s) = \infty \).

These assertions will be established in Section 8. Concerning the question which matter models besides Vlasov matter satisfy our conditions above we note the following:

**Remark.** For a spherically symmetric perfect fluid with density \( \mathcal{R} \), pressure \( P = \mathcal{P}(\mathcal{R}) \), and radial velocity field \( u \), the (DEC) and (NNP) conditions and Eqn. (3.2) respectively are satisfied provided that \( 0 \leq \mathcal{P}(\mathcal{R}) \leq \mathcal{R} \), which restricts the equation of state. The (GCC) condition holds for example with \( c_1 = \sqrt{2} \) if \(-e^\lambda u \geq 1\) on \( D \). In the kinetic context of the Vlasov model we derive analogous estimates on the particle level from conditions on the initial data.

### 4 Preliminaries

In this section we collect some general facts concerning the spherically symmetric Einstein-matter equations under the assumptions (DEC) and (NNP) that have been specified in the previous section.

A quantity which plays an important role is the quasi-local mass \( m(t, r) \). Typically, the spherically symmetric Einstein-matter system is supplemented by the requirement of a regular centre, i.e., \( \lambda(t, 0) = 0 \). Using this boundary condition the field equation (1.7) implies that
\[
e^{-2\lambda} = 1 - \frac{2m}{r}, \tag{4.1}
\]
where the quasi-local mass would be given by \( m(t, r) := \int_0^r 4\pi \eta^2 \rho(t, \eta) \, d\eta \). Then \( m(t, \infty) \) is a conserved quantity, the ADM mass. However, in the present context we want to investigate the system on the outer domain \( D \), regardless of whether or not the solution remains regular in the region \( r < \gamma^+(t) \). Hence we do not use the usual boundary condition at \( r = 0 \). Instead, we assume that the ADM mass \( M > 0 \) is given and redefine the quasi-local mass by
\[
m(t, r) = M - \int_r^\infty 4\pi \eta^2 \rho(t, \eta) \, d\eta. \tag{4.2}
\]
Then \( \lim_{r \to \infty} m(t,r) = M, \) \( 0 \leq m \leq M, \) and \( m_r = 4\pi r^2 \rho \) holds. Defining \( \lambda \) by (4.1), (3.1) shows that (1.7) and the boundary condition in (1.6) are satisfied. In addition, we need to modify (2.5) to
\[
\hat{m}(r) < \frac{r}{2}, \quad r \in [0, \infty[,
\]
a condition that once again will be included in the notion of regular initial data.

By (1.7) and (1.8),
\[
\lambda_r = \left( 4\pi \rho - \frac{m}{r^2} \right) e^{2\lambda}, \quad \mu_r = \left( \frac{m}{r^2} + 4\pi \rho \right) e^{2\lambda}.
\]
(4.4)
In view of (1.6), \( \mu = \hat{\mu} + \tilde{\mu}, \) where we define
\[
\hat{\mu}(t,r) := -\int_0^\infty \frac{m(t,\eta)}{\eta^2} e^{2\lambda(t,\eta)} \, d\eta,
\]
(4.5)
\[
\tilde{\mu}(t,r) := -\int_0^\infty 4\pi \eta p(t,\eta) e^{2\lambda(t,\eta)} \, d\eta.
\]
(4.6)

**Lemma 4.1** The following assertions hold.

(a) \( 2\hat{\mu} \leq \mu - \lambda \leq \hat{\mu} + \lambda. \)

(b) \( \mu + \lambda \leq \hat{\mu} + \lambda. \)

(c) \( (\mu - \lambda)(t,r) = 2\hat{\mu}(t,r) + \int_r^\infty 4\pi \eta (\rho - p)(t,\eta) e^{2\lambda(t,\eta)} \, d\eta. \)

(d) \( \hat{\mu}_t(t,r) = \int_r^\infty 4\pi j(t,\eta) e^{(\mu+\lambda)(t,\eta)} e^{2\lambda(t,\eta)} \, d\eta. \) In particular, if \( j \leq 0, \) then also \( \hat{\mu}_t \leq 0. \)

**Proof:** In view of (1.6),
\[
\lambda(t,r) = -\int_0^\infty \left( 4\pi \rho(t,\eta) - \frac{m(t,\eta)}{\eta^2} \right) e^{2\lambda} \, d\eta = -\int_0^\infty 4\pi \rho(t,\eta) e^{2\lambda} \, d\eta - \hat{\mu},
\]
and by (3.2) the relation \( \mu - \lambda \geq 2\hat{\mu} \) follows. On the other hand, by (4.1), \( \lambda \geq 0. \) Thus \( \hat{\mu} \leq 0 \) leads to \( \mu - \lambda \leq \mu \leq \hat{\mu} \leq \mu + \lambda, \) and part (a) is established. Part (b) follows from \( \hat{\mu} \leq 0. \) As to (c), we observe that
\[
\hat{\mu} + \lambda + \int_r^\infty 4\pi \eta (\rho - p) e^{2\lambda} \, d\eta = \tilde{\mu},
\]
which gives the claim. By (4.1) and (1.9), \( (e^{2\lambda}m)_t = \frac{1}{2\pi} (e^{2\lambda} - 1)_t = -4\pi e^{\mu+\lambda} e^{2\lambda} j. \) Hence (d) follows from (4.5).
Lemma 4.2 For \( r \in [0, \infty) \) the following holds:

\[
\int_r^\infty 4\pi \eta (\rho + p)(t, \eta) e^{(\mu+\lambda)(t, \eta)} e^{2\lambda(t, \eta)} d\eta = 1 - e^{(\mu+\lambda)(t, r)} \leq 1,
\]

\[
\int_r^\infty 4\pi \eta \rho(t, \eta) e^{(\hat{\mu}+\lambda)(t, \eta)} e^{2\lambda(t, \eta)} d\eta = 1 - e^{(\hat{\mu}+\lambda)(t, r)} \leq 1.
\]

**Proof:** It suffices to integrate

\[
\partial_r(e^{\mu+\lambda}) = e^{\mu+\lambda}(\mu_r + \lambda_r) = e^{\mu+\lambda}4\pi r (p + \rho),
\]

\[
\partial_r(e^{\hat{\mu}+\lambda}) = e^{\hat{\mu}+\lambda}(\hat{\mu}_r + \lambda_r) = e^{\hat{\mu}+\lambda}(e^{2\lambda} \frac{m}{\rho^2} + (4\pi r \rho - \frac{m}{\rho^2}) e^{2\lambda})
\]

\[
= 4\pi \rho e^{\hat{\mu}+\lambda} e^{2\lambda},
\]

(4.7)

observing that \( \lim_{r \to \infty} \hat{\mu}(t, r) = \lim_{r \to \infty} \lambda(t, r) = \lim_{r \to \infty} \rho(t, r) = 0 \). For Vlasov matter, the first relation has been used in [2, Lemma 1]. \( \square \)

Next we consider outgoing and ingoing radial null geodesics \( \gamma^+ \) and \( \gamma^- \), respectively.

Lemma 4.3 Let \( \gamma^\pm \) be the solutions to

\[
\frac{d\gamma^\pm}{ds}(s) = \pm e^{(\mu-\lambda)(s, \gamma^\pm(s))}, \quad \gamma^+(0) = r_0 < r_1 = \gamma^-(0).
\]

Then

(a) \( \gamma^+ \) is strictly increasing, \( s \mapsto m(s, \gamma^+(s)) \) is increasing, and the limits

\( \lim_{s \to \infty} \gamma^+(s) \in ]r_0, \infty] \) and \( \lim_{s \to \infty} m(s, \gamma^+(s)) \in [m(0, r_0), M] \) exist.

(b) \( \gamma^- \) is strictly decreasing, \( s \mapsto m(s, \gamma^-(s)) \) is decreasing, and the limits

\( \lim_{s \to \infty} \gamma^-(s) \in [0, r_1] \) and \( \lim_{s \to \infty} m(s, \gamma^-(s)) \in [0, m(0, r_1)] \) exist.

(c) The relation

\[
\frac{d}{ds}(\hat{\mu} + \lambda)(s, \gamma^\pm(s)) = \left( \hat{\mu}_t - 4\pi r e^{\mu+\lambda}(j \mp \rho) \right)|_{(t, r) = (s, \gamma^\pm(s))}
\]

holds. In particular, if \( j \leq 0 \) and \( \rho = j = 0 \) along \( \gamma^\pm \), then also

\[
\frac{d}{ds}(\hat{\mu} + \lambda)(s, \gamma^\pm(s)) \leq 0.
\]

**Proof:** Differentiating (4.1) w.r.t. \( t \) and using (1.9) implies that \( m_t = -4\pi r^2 e^{\mu-\lambda} j \). Since \( \rho \geq j \) according to (3.2), this yields

\[
\frac{d}{ds} m(s, \gamma^+(s)) = m_t(s, \gamma^+(s)) + m_r(s, \gamma^+(s)) \frac{d\gamma^+}{ds}(s)
\]

\[
= (-4\pi r^2 e^{\mu-\lambda} j + 4\pi r^2 \rho e^{\mu-\lambda})|_{(t, r) = (s, \gamma^+(s))} \geq 0.
\]
Thus part (a) is obtained from $m \leq M$. Since $\rho \geq -j$, the proof of (b) is analogous to (a). As to (c), note that by definition of $\hat{\mu}$, (1.7), and (1.9),

\[
\frac{d}{ds}(\hat{\mu} + \lambda)(s, \gamma^{\pm}(s)) = \left(\hat{\mu}_t + \hat{\mu}_r \frac{d\gamma^{\pm}}{ds} + \lambda_t + \lambda_r \frac{d\gamma^{\pm}}{ds}\right)_{(t,r)=(s,\gamma^{\pm}(s))}
\]

\[
= \left(\hat{\mu}_t \pm \frac{m}{r^2} e^{2\lambda} e^{\mu-\lambda} - 4\pi r e^{\mu+\lambda} j \pm \left(4\pi r \rho - \frac{m}{r^2}\right) e^{2\lambda} e^{\mu-\lambda}\right)_{(t,r)=(s,\gamma^{\pm}(s))}
\]

\[
= \left(\hat{\mu}_t - 4\pi r e^{\mu+\lambda}(j \mp \rho)\right)_{(t,r)=(s,\gamma^{\pm}(s))},
\]

as desired. The last claim follows from Lemma 4.1(d).

5 Proof of Theorem 3.1

In this section we use the hypotheses stated in Section 3 to prove Theorem 3.1. The proof is short and emphasizes that the crucial mechanism is captured in the (GCC) condition. Our main results which show in particular that the (GCC) condition holds for Vlasov matter are established in the next sections.

Consider the out- and ingoing null geodesics $\gamma^+$ and $\gamma^-$ defined in Lemma 4.3. The claims follow if we can show that these geodesics never intersect. By continuity and monotonicity there exists $T \in [0, \infty]$ such that

\[
r_0 \leq \gamma^+(t) < \gamma^-(t) \leq r_1, \quad t \in [0, T];
\]

it will be shown that actually $T = \infty$ holds. In view of (2.9) we have initially that $\rho = p = j = 0$ for $r \geq R_1$. The (GCC) condition implies that $j \leq 0$ in $D$, meaning that the flow of matter is ingoing. Therefore

\[
\rho = p = j = 0 \quad \text{and} \quad m = M \quad \text{for} \quad (t,r) \in [0, T] \times [R_1, \infty].
\]

By Lemma 4.2, (3.2), the (GCC) condition, and Lemma 4.1(d) for $s \in [0, T]$. 

19
and \( r \in [\gamma^+(s), \infty[ \),

\[
1 - e^{(\mu+\lambda)(s,r)} = \int_r^\infty 4\pi \eta (\rho + p)(s, \eta) e^{(\mu+\lambda)(s,\eta)} e^{2\lambda(s,\eta)} \, d\eta
\]

\[
\leq 2c_1 \int_r^\infty 4\pi \eta |j(s,\eta)| e^{(\mu+\lambda)(s,\eta)} e^{2\lambda(s,\eta)} \, d\eta
\]

\[
\leq -2c_1 R_1 \int_r^\infty 4j(s,\eta) e^{(\mu+\lambda)(s,\eta)} e^{2\lambda(s,\eta)} \, d\eta
\]

\[
= -2c_1 R_1 \hat{\mu}(s,r),
\]

since \( j(s,\eta) \neq 0 \) implies \( \eta \leq R_1 \). Thus

\[
\hat{\mu}(s,r) \leq -\frac{1}{2c_1 R_1} \left( 1 - e^{(\mu+\lambda)(s,r)} \right).
\]  \hspace{1cm} (5.3)

This in turn implies that

\[
\hat{\mu}(t,\gamma^\pm(t)) - \hat{\mu}(0,\gamma^\pm(0))
\]

\[
= \int_0^t \frac{d}{ds} \hat{\mu}(s,\gamma^\pm(s)) \, ds
\]

\[
= \int_0^t \left( \hat{\mu}_t(s,\gamma^\pm(s)) + \hat{\mu}_\tau(s,\gamma^\pm(s)) e^{(\mu-\lambda)(s,\gamma^\pm(s))} \right) \, ds
\]

\[
\leq \int_0^t \left( -\frac{1}{2c_1 R_1} \left( 1 - e^{(\mu+\lambda)(s,\gamma^\pm(s))} \right) + \frac{m(s,\gamma^\pm(s))}{\gamma^\pm(s)^2} e^{(\mu+\lambda)(s,\gamma^\pm(s))} \right) \, ds
\]

\[
\leq -\frac{t}{2c_1 R_1} + \int_0^t \left( \frac{1}{2c_1 R_1} + \frac{m(s,\gamma^\pm(s))}{\gamma^\pm(s)^2} \right) e^{(\mu+\lambda)(s,\gamma^\pm(s))} \, ds.
\]  \hspace{1cm} (5.4)

Now for any \( r \in [r_0, r_1] \) and \( t \in [0, T] \) it follows from \( \hat{\mu}_r \geq 0 \) and (4.1) that

\[
\hat{\mu}(t, r) \leq \hat{\mu}(t, R_1) = -\int_{R_1}^\infty \frac{M \, d\eta}{\eta^2(1-2M/\eta)}.
\]  \hspace{1cm} (5.5)

Using \( M = r_1/2 \) we get

\[
\hat{\mu}(t, R_1) = \frac{1}{2} \log \left( \frac{R_1 - r_1}{R_1} \right),
\]

so that for \( r \in [r_0, r_1] \),

\[
e^{\hat{\mu}(t,r)} \leq e^{\hat{\mu}(t,R_1)} = \sqrt{\frac{R_1 - r_1}{R_1}}.
\]  \hspace{1cm} (5.6)
By (3.3) and the properties of the initial matter distribution there is vacuum in the region $\gamma^+(t) \leq r \leq \gamma^-(t)$. Hence $m(t, r) = M - M_{\text{out}}$ and (2.6) imply that
\[ e^\lambda(t, r) \leq \frac{1}{\sqrt{1 - 2(M - M_{\text{out}})/r_0}} < 3 \quad (5.7) \]
for $\gamma^+(t) \leq r \leq \gamma^-(t)$. From Lemma 4.1(b) and (2.8), recalling $\kappa = 2c_1$, we obtain in particular that
\[ e^{(\mu + \lambda)(s, \gamma^+(s))} \leq e^{(\hat{\mu} + \lambda)(s, \gamma^+(s))} < \min \left\{ \frac{1}{2}, \frac{r_0^2}{8c_1 R_1 M} \right\} =: d. \]
Thus (5.4) yields
\[
\hat{\mu}(t, \gamma^+(t)) - \hat{\mu}(0, \gamma^+(0)) \leq -\frac{t}{2c_1 R_1} + d \int_0^t \left( \frac{1}{2c_1 R_1} + \frac{M}{r_0^2} \right) ds \\
= -\left( \frac{1 - d}{2c_1 R_1} - \frac{M}{r_0^2} \right) t \\
\leq -\left( \frac{1}{4c_1 R_1} - \frac{M}{r_0^2} \right) t \\
\leq -\frac{t}{8c_1 R_1}, \quad t \in [0, T].
\]
Hence Lemma 4.1(a) leads to the estimate
\[
|\gamma^+(t) - \gamma^+(0)| = \left| \int_0^t e^{(\mu - \lambda)(s, \gamma^+(s))} ds \right| \leq \int_0^t e^{\hat{\mu}(s, \gamma^+(s))} ds \\
\leq e^{\hat{\mu}(0, \gamma^+(0))} \int_0^t e^{-\frac{s}{8c_1 R_1}} ds \leq 8c_1 R_1 \sqrt{\frac{R_1 - r_1}{R_1}},
\]
where we used (5.6) in the last inequality. By the third condition in (2.8),
\[
\sqrt{\frac{R_1 - r_1}{R_1}} < \frac{r_1 - r_0}{16c_1 R_1},
\]
so that
\[
|\gamma^+(t) - \gamma^+(0)| < \frac{r_1 - r_0}{2}, \quad t \in [0, T].
\]
Since $\gamma^-(0) - \gamma^+(0) = r_1 - r_0$, this implies that $\gamma^-(T) - \gamma^+(T) > 0$. Hence, if we choose $T$ in (5.1) to be maximal, then $T = \infty$, i.e., $\gamma^+$ and $\gamma^-$ do never intersect. This completes the proof of Theorem 3.1. \[\square\]
Remark. In the above proof we have obtained the more explicit information that

\[ \lim_{s \to \infty} \gamma^+(s) < \frac{r_0 + r_1}{2}, \quad m(s, \gamma^+(s)) = M - M_{\text{out}}, \quad s \geq 0, \] (5.8)

the latter since all the matter originally to the right of \( \gamma^-(s) > \gamma^+(s) \) necessarily stays there.

6 Proof of Theorem 2.2

We first check that the (DEC), (NNP), and (GLO) conditions hold for Vlasov matter. Then we show that there exists a class of initial data such that the corresponding solutions satisfy the (GCC) condition with \( c_1 = 3 \). Hence Theorem 2.2 will follow from Theorem 3.1.

The characteristic system associated to the Vlasov equation (2.1) is

\[
\frac{dR}{ds} = e^{(\mu - \lambda)(s,R)} \frac{W}{E}, \quad (6.1)
\]

\[
\frac{dW}{ds} = -\lambda_t(s,R)W - e^{(\mu - \lambda)(s,R)} \mu_t(s,R)E + e^{(\mu - \lambda)(s,R)} \frac{L}{R^3 E}, \quad (6.2)
\]

\[
\frac{dL}{ds} = 0. \quad (6.3)
\]

If \( s \mapsto (R, W, L)(s) \) is a solution with data \( (R, W, L)(0) = (r, w, L) \), then

\[ f(s, R(s), W(s), L) = \hat{f}(r, w, L) \]

is constant in \( s \). Hence \( (R(s), W(s), L) \in \text{supp} f(s) \iff (r, w, L) \in \text{supp} \hat{f} \). Such characteristics will be addressed as characteristics in \( \text{supp} f \).

Direct inspection of the definition in (2.3) shows that (NNP) holds for Vlasov matter. It is moreover well-known that the (DEC) condition is satisfied for Vlasov matter; see [1, Sec. 1.4]. Alternatively, we can check (3.2) and (3.3) directly. The latter follows from (6.1) above, whereas the former is a consequence of the expressions for the matter terms given in (2.2), (2.3), and (2.4).

To see that the (GLO) condition holds for any regular initial data set we argue as follows. First of all, a regular initial data launches a local-in-time solution on some time interval \([0, T]\), and the corresponding theorems in [25] or [24] also give a condition under which this local solution can be extended to a global one. In order to see that the local solution can always be extended to the whole outer domain \( D \) we first observe that the spherically
symmetric Einstein-Vlasov system on $D$, with (4.1) and (4.2) replacing the usual boundary condition of a regular centre and with (1.10) included, has again a well-posed initial value problem for regular data supported in $]r_0, \infty[$. This can be shown in the same way as for the system on the whole space, the essential point being that no characteristic of the Vlasov equation can enter region $D$ at the boundary $r = \gamma^+(t)$. To the local solution on $D$ we can now apply the arguments from [28] and conclude that the solution exists on all of $D$. This is possible due to the fact that the estimates in [28] address a situation where matter is bounded away from the centre or is controlled in a neighborhood of the centre so that these estimates can be applied on $D$. We emphasize that for our present analysis only the behaviour of the solution on $D$ plays a role. We have chosen to present our results in the form that we have Vlasov matter also inside $r < \gamma^+(t)$, and this part of the solution may or may not break down, but this is irrelevant for our arguments.

Hence it remains to show that the (GCC) condition holds. To this end we let $0 < r_0 < r_1 < R_1$, $R_0 = (r_1 + R_1)/2$, and $M = r_1/2$. For a parameter $W_- < 0$ to be specified below and regular data $\hat{f}$ with ADM mass $M$ we formulate the following

**General support condition:** For all $(r, w, L) \in \text{supp } \hat{f}$ the following holds:

$$r \in ]0, r_0] \cup [R_0, R_1],$$

and if $r \in [R_0, R_1]$ then

$$w \leq W_-$$

and also

$$0 < L < \frac{3L}{\eta} \hat{\mu}(\eta) + \eta \hat{n}(\eta), \eta \in [r_0, R_1].$$

(6.4)

We use the notation $\hat{\mu}$ when $\rho = \hat{\rho}$ in (4.2). Furthermore, we abbreviate

$$\Gamma = \Gamma(r_1, R_1) := \sqrt{\frac{R_1 - r_1}{R_1 + r_1}}.$$  

(6.5)

The following lemma shows that if the support condition holds, then the particles in the outer domain $D$ keep moving inward in a controlled way.

**Lemma 6.1** Let $\hat{f}$ be regular and satisfy the general support condition for some $W_- < 0$. Then for all $(r, w, L) \in \text{supp } f(t)$ such that $(t, r) \in D$,

$$w \leq \Gamma(r_1, R_1)W_-.$$ 

In particular, $j \leq 0$ on $D$. 

23
Proof: Let \([0, T]\) denote the maximal time interval such that for \(t < T\)

\[
w < 0 \text{ for } (r, w, L) \in \text{supp} \ f(t) \text{ with } (t, r) \in D.
\]  

(6.6)

Since \(W_0 < 0, T > 0\) by continuity. By the definition of \(j\),

\[
j(t, r) \leq 0 \text{ for } (t, r) \in D_T := D \cap ([0, T] \times [0, \infty]).
\]  

(6.7)

Let \((R, W, L)(s)\) be a characteristic in \(\text{supp} \ f\). Then

\[
\frac{d}{ds}(e^{-\lambda W}) = -e^{-\lambda}(W \lambda_t + W \lambda_r \frac{dR}{ds} - \frac{dW}{ds})
\]

\[
= 4\pi R \frac{E}{E} e^\mu (2WEj - W^2 \rho - E^2 p) + e^\mu \left(1 - \frac{2m}{R}\right) \frac{L}{R^3 E}
\]

\[
+ e^\mu m \frac{r^2}{R^2} \left(\frac{w^2}{E} - E\right)
\]

\[
= -4\pi^2 \frac{E}{R} e^\mu \int_{-\infty}^{\infty} \int_0^\infty \left[\sqrt{\frac{E}{E}} w - \sqrt{\frac{E}{E}} \tilde{w}\right]^2 f \tilde{dL} \tilde{d\tilde{w}}
\]

\[
- e^\mu m \frac{R}{R^2} \left(\frac{1 + L/R^2}{E} + \frac{2L}{R^2 E} + e^\mu \frac{L}{R^3 E}\right),
\]

where \(E = E(R, W, L)\) and \(\tilde{E} = \tilde{E}(R, \tilde{w}, \tilde{L})\). Therefore

\[
\frac{d}{ds}(e^{-\lambda W}) \leq -e^\mu m \frac{R}{R^2} \left(\frac{1 + L/R^2}{E} + \frac{2L}{R^2 E} + e^\mu \frac{L}{R^3 E}\right) + e^\mu \frac{L}{R^3 E}.
\]

Differentiating (4.1) w.r.t. \(t\) and using (1.9) leads to \(m_t = -4\pi r^2 e^{\mu - \lambda} j\), which by (6.7) is non-negative on \(D_T\). It follows that \(m(s, r) \geq m(0, r) = \hat{m}(r)\). Thus as long as the characteristic remains in \(D_T\),

\[
\frac{d}{ds}(e^{-\lambda W}) \leq -e^\mu \frac{R}{R^2} \left(\frac{1 + L/R^2}{E} + \frac{2L}{R^2 E} + e^\mu \frac{L}{R^3 E}\right) + e^\mu \frac{L}{R^3 E}
\]

\[
= e^\mu \frac{1}{R^3 E} \left(L - 3L/R \hat{m}(R) - R \hat{m}(R)\right).
\]

Now \(R(0) \in [R_0, R_1]\) and \(\hat{R}(s) \leq 0\) by (6.1) and (6.6) yields \(R_1 \geq R(0) \geq R(s) \geq \gamma^+(s) \geq r_0\). Hence condition (6.4) implies that, as long as the characteristic remains in \(D_T\), \(\frac{d}{ds}(e^{-\lambda W}) < 0\), so that

\[
W(s) \leq e^{\lambda(s, R(s)) - \lambda(0, R(0))} W_-.
\]
But $\lambda \geq 0$, so $W_- < 0$ leads to

$$W(s) \leq \left( \min_{r \in [r_0, R_1]} e^{-\lambda(0, r)} \right) W_-.$$  

In view of (4.1),

$$e^{-\lambda(0, r)} \geq \sqrt{1 - \frac{2M}{R_0}} = \sqrt{\frac{R_1 - r_1}{R_1 + r_1}}, \quad r \in [R_0, R_1],$$

and recalling (6.5) it follows that

$$W(s) \leq \Gamma(r_1, R_1) |W_-| < 0$$

as long as the characteristic remains in $D_T$. By the maximality of $T$ in (6.6), $T = \infty$, and the proof is complete. \qed

In order to specify the initial data set $I_2$, let $r_0, r_1, M_1, M_{out}$ be given as in Section 2 and let $R_1$ be such that (2.8) holds for $\kappa = 6$. We require that $W_- < 0$ satisfies the estimate

$$\Gamma(r_1, R_1) |W_-| \geq 1. \quad (6.8)$$

Then

$$I_2 := \left\{ \hat{f} \mid \hat{f} \text{ is regular, satisfies (2.9), (2.10), the general support condition,} \right.$$ \hspace{1cm} 

$$\text{and for } (r, w, L) \in \text{supp} \hat{f} \text{ with } r \in [R_0, R_1], \sqrt{L/r_0} \leq \Gamma |W_-| \right\}. \quad (6.9)$$

Consider now a solution $f$ launched by initial data from this set. Condition (6.8) and Lemma 6.1 imply that

$$|w| \geq \Gamma(r_1, R_1) |W_-| \geq 1 \quad \text{on} \quad \text{supp} f \cap D, \quad (6.10)$$

and since $L$ is conserved along characteristics, (6.9) leads to $\sqrt{L/r} \leq |w|$ for all particles in $\text{supp} f \cap D$. Hence the definition (2.2) of $\rho$ implies that on $D$,

$$\rho(t, r) \leq \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_0^\infty f \ dL \ dw + \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_0^\infty |w| f \ dL \ dw$$

$$+ \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_0^\infty \sqrt{L/r} \ f \ dL \ dw$$

$$\leq 3 \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_0^\infty |w| f \ dL \ dw = 3 |j(t, r)|. \quad (6.11)$$
Accordingly, $I_2$ satisfies the (GCC) condition with $c_1 = 3$, and Theorem 2.2 follows from Theorem 3.1.

We briefly show that the set $I_2$ is far from empty. Therefore fix $0 < r_0 < r_1 < R_0 < R_1$, $M = r_1/2$, and $0 < M_{\text{out}} < M$ such that $R_0 = (r_1 + R_1)/2$, (2.6), and (2.8) are satisfied. Let $0 \leq f_1 \in C^1$ have $r$-support in $[r_0 - \delta, r_0]$ for some $0 < \delta < r_0/9$, and let $0 \leq f_2 \in C^1$ have $r$-support in $[R_0, R_1]$. Fix the compact $w$-support of $f_2$ in $]-\infty, W_-]$ with $W_- < 0$ such that (6.8) holds, and fix its $L$-support in $[0, L_2]$ so that

$$\frac{\sqrt{L_2}}{r_0} \leq \Gamma(r_1, R_1) |W_-|$$

and

$$L < (M - M_{\text{out}}) \left( \frac{3L}{\eta} + \eta \right), \quad L \in [0, L_2], \quad \eta \in [r_0, R_1].$$

Now take $\hat{f} = Af_1 + Bf_2$, where $A > 0$ and $B > 0$ are chosen such that (2.9) and (2.10) are satisfied. Note that $\hat{m}(\eta) \geq M - M_{\text{out}}$ for $\eta \in [r_0, R_1]$, whence (6.4) holds as well; thus the general support condition if verified. It remains to check (4.3). If $r \in [0, r_0 - \delta]$, then $\hat{m}(r) = 0$. If $r \in [r_0 - \delta, R_0]$, then $\hat{m}(r) \leq M - M_{\text{out}}$ yields in view of (2.6),

$$\frac{2\hat{m}}{r} \leq \frac{2(M - M_{\text{out}})}{r_0 - \delta} < 1.$$ 

If $r \in [R_0, \infty]$, then

$$\frac{2\hat{m}}{r} \leq \frac{2M}{R_0} < 1,$$

since $2M = r_1 < R_0$. Hence $\hat{f}$ is regular and has all the properties that are required in the definition of $I_2$.

**Remark.** The set $I_2$ has “non-empty interior”, in the sense that sufficiently small perturbations of initial data in the “interior” of this set belong to $I_2$ as well, provided that the support is changed very little and $M$ is left invariant. This is due to the fact that the various parameters entering into the definition of $I_2$ are defined in terms of inequalities and hence can be varied.

### 7 Proof of Theorem 2.1

The set up is closely related to the set up in the proof of Theorem 2.2. As we saw above, the (DEC), (NNP), and (GLO) conditions are satisfied for Vlasov matter, and we will again construct an initial data set such that the
(GCC) condition holds with $c_1 = 3$. However, since this result relies on condition (2.7) instead of (2.8), we cannot simply invoke Theorem 3.1 after the (GCC) condition has been verified; instead an additional step needs to be added to the proof. For this new argument a slightly stronger condition on the momentum variable $w$ needs to be imposed on $\text{supp} \hat{f}$. We now require that $W_- < 0$ satisfies
\begin{equation}
\Gamma(r_1, R_1)^2 |W_-|^2 \geq \frac{10}{d},
\end{equation}
where
\[ d := \min \left\{ \frac{1}{2}, \frac{r_0}{12R_1}, \frac{r_1 - r_0}{300R_1} \right\}. \]
Then
\[ I_1 := \left\{ \hat{f} \mid \hat{f} \text{ is regular, satisfies (2.9), (2.10), the general support condition, and for } (r, w, L) \in \text{supp} \hat{f} \text{ with } r \in [R_0, R_1], \sqrt{L}/r_0 \leq 1 \right\}. \]
The same construction as at the end of the previous section shows that this set is not empty, and the same remark as at the end of the previous section applies.

Let $f$ be a solution launched by initial data from $I_1$. It is clear from these conditions that Lemma 6.1 applies, and since $10/d \geq 1$, it follows that (6.10) holds as well. Thus the argument leading to $\rho \leq 3|j|$ on $D$ in the proof of Theorem 2.2 applies again. Hence, the (GCC) condition is satisfied with $c_1 = 3$.

Consider the expression
\[ \rho(s, r) - p(s, r) = \frac{\pi}{r^2} \int_{-\infty}^{\infty} \int_{0}^{\infty} \left( E - \frac{w^2}{E} \right) f(s, r, w, L) dL dw. \]
Since $E^2 \geq w^2 \geq \Gamma^2(r_1, R_1) W^2$ by Lemma 6.1, we get for $r \in [\gamma^+(s), R_1]$ from $\sqrt{L}/r_0 \leq 1$,
\begin{equation}
E - \frac{w^2}{E} = \frac{1}{E} (E^2 - w^2) = \frac{1}{E} \left( 1 + \frac{L}{r^2} \right) \leq \frac{2}{E} \leq \frac{2}{\Gamma^2 W^2} E =: c_0 E,
\end{equation}
so that
\[ \rho(s, r) - p(s, r) \leq c_0 \rho(s, r). \]
After this preparation, we again show that the out- and ingoing null geodesics $\gamma^+$ and $\gamma^-$ do not intersect. We choose $T \in [0, \infty]$ such that (5.1) holds. In this case we cannot rely on the smallness of $e^{\mu}$ as in the proof of
Theorem 3.1, so we need to control the evolution also when $e^\mu$ is not small. For this part the estimate (7.4) is essential.

We fix $t_+ \in [0, T]$ by requiring that

$$e^{(\hat{\mu} + \lambda)(s, \gamma^+(s))} > d \text{ for } s \in [0, t_+] \quad \text{and} \quad e^{(\hat{\mu} + \lambda)(s, \gamma^-(s))} \leq d \text{ for } s \in [t_+, T].$$

First we note that $t_+$ is well-defined, since by Lemma 4.3(c),

$$\frac{d}{ds} e^{(\hat{\mu} + \lambda)(s, \gamma^+(s))} \leq 0. \quad (7.5)$$

\textit{Step 1:} Consider $s \in [0, t_+]$; if $t_+ = 0$, then this step is omitted. For $\eta \geq \gamma^+(s)$,

$$d \leq e^{(\hat{\mu} + \lambda)(s, \gamma^+(s))} \leq e^{(\hat{\mu} + \lambda)(s, \eta)},$$

since $(\hat{\mu} + \lambda)_r = 4\pi r\rho e^{2\lambda} \geq 0$ by (4.7). Hence Lemma 4.1(c) and (7.4) yield

$$(\mu - \lambda)(s, \gamma^+(s)) = 2\hat{\mu}(s, \gamma^+(s)) + \int_{\gamma^+(s)}^{\infty} 4\pi \eta (\rho - p)(s, \eta) e^{2\lambda(s, \eta)} d\eta$$

$$\leq 2\hat{\mu}(s, \gamma^+(s)) + \frac{c_0}{d} \int_{\gamma^+(s)}^{\infty} 4\pi \eta \rho(s, \eta) e^{(\hat{\mu} + \lambda)(s, \eta)} e^{2\lambda(s, \eta)} d\eta$$

$$\leq 2\hat{\mu}(s, \gamma^+(s)) + \frac{c_0}{d},$$

where for the last estimate Lemma 4.2 has been used.

Now we make the following observation: There is at least one characteristic $(\bar{R}, \bar{W}, \bar{L})(s)$ with $\bar{R}(0) \in [R_0, R_1]$, which does not leave the strip $[r_1, R_1]$ during the finite time interval $[0, T]$. In fact, if at time $t = T$ all characteristics had left the strip $[r_1, R_1]$ (and thus had entered the region $r < r_1$), then $m(T, r_1) = M$. From (4.1) and $2M = r_1$ it would follow that $\lambda(T, r_1) = \infty$. However, this contradicts the (GLO) condition which holds for Vlasov matter.

Since $\gamma^+(s) \leq r_1 \leq \bar{R}(s)$, and since $\bar{\mu}_r \geq 0$, we thus obtain in view of Lemma 4.1(a) that

$$(\mu - \lambda)(s, \gamma^+(s)) \leq 2\hat{\mu}(s, \gamma^+(s)) + \frac{c_0}{d} \leq 2\hat{\mu}(s, \bar{R}(s)) + \frac{c_0}{d}$$

$$\leq (\mu - \lambda)(s, \bar{R}(s)) + \frac{c_0}{d}, \quad s \in [0, t_+].$$

Next note that $|W| \geq 1$ by (6.10), and hence due to (6.1) and observing $\bar{R}^2 \geq r_0^2 \geq L$,

$$|\dot{\bar{R}}| = \frac{|W|}{E} e^{\mu - \lambda} \geq \frac{|W|}{\sqrt{2 + W^2}} e^{\mu - \lambda} \geq \frac{1}{2} e^{\mu - \lambda}.$$
Therefore for all $t \in [0, t^+_*]$ the estimate

$$|\gamma^+(t) - \gamma^+(0)| = \left| \int_0^t \pm e^{(\mu - \lambda)(s, \gamma^+(s))} ds \right| \leq e^{c_0} \int_0^t e^{(\mu - \lambda)(s, \hat{R}(s))} ds$$

$$\leq -2e^{c_0} \int_0^t \hat{R}(s) ds = 2e^{c_0} (\hat{R}(0) - \hat{R}(t))$$

$$\leq 2e^{c_0} (R_1 - r_1)$$  (7.6)

is obtained.

**Step 2:** Let $t \in [t^+_*, T]$; if $t^+_* = T$, then this step is omitted. The arguments here are basically the ones presented in Section 5. The computation leading to (5.4) is almost identical, and

$$\tilde{\mu}(t, \gamma^+(t)) - \tilde{\mu}(t^+_*, \gamma^+(t^+_*))$$

$$\leq -\frac{t - t^+_*}{2c_1 R_1} + \int_{t^+_*}^t \left( \frac{1}{2c_1 R_1} + \frac{m(s, \gamma^+(s))}{\gamma^+(s)^2} \right) e^{(\mu + \lambda)(s, \gamma^+(s))} ds$$  (7.7)

for $c_1 = 3$. By Lemma 4.1(b), $e^{(\mu + \lambda)(s, \gamma^+(s))} \leq e^{(\mu^+ + \lambda)(s, \gamma^+(s))} \leq d$. Next we use the facts that $m/r < 1/2$, $\gamma^+(s) \geq r_0$, and the definition of $d$ to obtain the estimate

$$\tilde{\mu}(t, \gamma^+(t)) - \tilde{\mu}(t^+_*, \gamma^+(t^+_*)) \leq -\frac{1}{2c_1 R_1} (t - t^+_*) + d \int_{t^+_*}^t \left( \frac{1}{2c_1 R_1} + \frac{1}{2r_0} \right) ds$$

$$= -\left( \frac{1 - d}{2c_1 R_1} - d \frac{1}{2r_0} \right) (t - t^+_*)$$

$$\leq -\left( \frac{1}{4c_1 R_1} - d \frac{1}{2r_0} \right) (t - t^+_*)$$

$$\leq -\frac{1}{8c_1 R_1} (t - t^+_*), \quad t \in [t^+_*, T].$$

Hence by Lemma 4.1(a),

$$|\gamma^+(t) - \gamma^+(t^+_*)| = \left| \int_{t^+_*}^t e^{(\mu - \lambda)(s, \gamma^+(s))} ds \right| \leq \int_{t^+_*}^t e^{\tilde{\mu}(s, \gamma^+(s))} ds$$

$$\leq e^{\tilde{\mu}(t^+_*, \gamma^+(t^+_*))} \int_{t^+_*}^t e^{-\frac{(s - t^+_*)}{2c_1 R_1}} ds$$

$$\leq e^{(\mu + \lambda)(t^+_*, \gamma^+(t^+_*))} \int_{t^+_*}^\infty e^{-\frac{(s - t^+_*)}{2c_1 R_1}} ds \leq 8c_1 R_1 d.$$  (7.8)

Adding the contributions (7.6) from Step 1 and (7.8) from Step 2, the final estimate

$$|\gamma^+(t) - \gamma^+(0)| \leq 2e^{c_0/d}(R_1 - r_1) + 8c_1 R_1 d$$
is obtained for all \( t \in [0, T] \). From (7.3) and (7.1) we have \( c_0/d \leq 1/5 \). The third condition on \( d \) together with (2.7) thus imply that
\[
|\gamma^\pm(t) - \gamma^\pm(0)| < \frac{r_1 - r_0}{2}.
\]
As in the proof of Theorem 3.1 we conclude that \( \gamma^+ \) and \( \gamma^- \) do not intersect, completing the proof of Theorem 2.1.

**Remarks.** (a) The sharper estimates stated in (5.8) clearly hold also in this case.
(b) The solution must necessarily enter the regime of Step 2, more precisely,
\[
\lim_{s \to \infty} e^{(\hat{\mu} + \lambda)(s, \gamma^\pm(s))} = 0
\]
for both null geodesics. Otherwise, the monotonicity implied by Eqn. (7.5) yields a positive constant \( c > 0 \) such that \( e^{(\hat{\mu} + \lambda)(s, \gamma^\pm(s))} > c \) for all time, and hence,
\[
|\dot{\gamma}^\pm| = e^{(\hat{\mu} - \lambda)} = e^{(\mu + \lambda)}e^{2\lambda} > ce^{\hat{\mu} - 2\lambda}.
\]
Since no matter can cross the two null geodesics,
\[
(\hat{\mu} - 2\lambda)(s, r) = \int_r^\infty 4\pi\eta(2p - p)e^{2\lambda}d\eta + 2\hat{\mu}(s, r) \\
\geq 2\hat{\mu}(s, r) = -2\int_r^\infty \frac{\hat{m}(r_0)}{\eta^2} \frac{1}{1 - 2\hat{m}(r_0)/\eta} d\eta \\
= \ln \frac{r - 2\hat{m}(r_0)}{r}
\]
for \( r = \gamma^\pm(s) \). If we insert this into the estimate for \( \dot{\gamma}^\pm \) it follows that this quantity is bounded from below by a positive constant which contradicts the finite limits of \( \gamma^\pm(s) \) as \( s \to \infty \).

It remains to prove Cor. 2.3.

**Proof of Corollary 2.3:** Let \( f_s \) be a static solution. By [3], \( 2m_s(r)/r < 8/9 \) for \( r > 0 \) where \( m_s \) is the local ADM mass induced by \( f_s \). In particular, \( M_s < r_s/2 < r_1/2 = M \), and (2.6) holds. As described above we can now specify the matter distribution for \( r \geq r_0 \), and we obtain initial data \( \tilde{f} \) in \( \mathcal{I}_1 \) or in \( \mathcal{I}_2 \) which coincide with the given static solution for \( 0 \leq r \leq r_0 \).

Since no matter travels from the outer domain \( D \) to the inner one where \( r \leq \gamma^+(t) \), the only way the matter in the outer domain can affect the static solution is through the metric. Consider the time-independent version of the Vlasov equation (2.1). Dropping all the time derivatives we see that in the
remaining equation the factor $e^{\lambda - \mu}$ can be canceled. Therefore, the static Einstein-Vlasov system is formulated in terms the quantities $f, \lambda$, and $\mu$, but not $\mu$ itself. By (4.1) and (4.4), $\lambda$ and $\mu_r$ are on $r \leq \gamma^+(t)$ not affected by the matter in the outer domain $D$, and therefore $f = f_s, \lambda, \mu_r$ remain time-independent for $r \leq \gamma^+(t)$.

Notice that the metric coefficient $\mu$ of course does change on the interior region, cf. Thm 2.4 (b).

8 Proof of Theorem 2.4

As a first step we estimate $\mu - \lambda$ from below for $r > 2M$, using Lemma 4.1 (a):

$$\begin{align*}
(\mu - \lambda)(t, r) &\geq 2\mu(t, r) = -2 \int_r^\infty \frac{m(t, \eta)}{\eta^2} e^{2\lambda(t, \eta)} d\eta \\
&= -2 \int_r^\infty \frac{m(t, \eta)}{\eta (\eta - 2m(t, \eta))} d\eta \geq -2 \int_r^\infty \frac{M}{\eta (\eta - 2M)} d\eta \\
&= \ln \frac{r - 2M}{r}, \quad r > 2M.
\end{align*}$$

Now consider any characteristic in the matter support, and let $R(t)$ denote its radial coordinate. Then by Lemma 6.1 and as long as $R(t) > 2M$,

$$\frac{dR}{ds} = e^{(\mu - \lambda)(s, R)} \frac{W}{E} \leq -Ce^{(\mu - \lambda)(s, R)} \leq -C \frac{R - 2M}{R};$$

for initial data from the set $I_1$ respectively $I_2$ one can take $C := \Gamma |W_-| / \sqrt{2 + \Gamma^2 W_-^2}$ respectively $C := 1 / \sqrt{3}$. Integrating this differential inequality we find that as long as $R(t) > 2M$ the estimate

$$-Ct \geq \int_{R(0)}^{R(t)} \frac{r}{r - 2M} dr = R(t) - R(0) + 2M \ln \frac{R(t) - 2M}{R(0) - 2M}$$

holds, and hence

$$R(t) \leq 2M + (R_1 - 2M) e^{\frac{1}{2M} (R_1 - 2M - Ct)},$$

which proves the support estimate in part (a). Since all the matter, which has ADM mass $M$, is contained in the region where $r \leq 2M + \alpha e^{-\beta t} =:\n
31
\(\sigma(t)\), the assertion on the metric follows. Moreover, for any \(r \leq \sigma(t)\) the monotonicity of \(\mu\) with respect to \(r\) implies that

\[
\mu(t, r) \leq \mu(t, \sigma(t)) = \hat{\mu}(t, \sigma(t)) = \ln \left( \frac{\sigma(t) - 2M}{\sigma(t)} \right)^{1/2},
\]

which is the first assertion of part (b). The second follows immediately since the integral \(\int_0^\infty e^{\mu(t,r)} dt\) is the proper length of a coordinate line of constant \(r, \theta, \) and \(\varphi\) in the outer region \(D\). This completes the proof of part (b).

As to (c) we first observe that any radially outgoing null geodesic which enters the region \(r > 2M\) escapes to \(r = \infty\) and is future complete, since by part (a) the metric on \(r > 2M + \epsilon\) where \(\epsilon > 0\) is arbitrary eventually equals the Schwarzschild one for which the asserted properties of the geodesics hold. Now consider the extremal geodesic \(\gamma^*\). If there existed some time \(t > 0\) such that \(\gamma^*(t) > 2M\), then by continuous dependence on the initial data the same would be true for all radially outgoing null geodesics with \(\gamma(0)\) sufficiently close to but less than \(r^*\). Hence such geodesics would escape to \(r = \infty\) in contradiction to the definition of \(r^*\). This shows that the extremal, radially outgoing null geodesic \(\gamma^*\) has the property that \(\lim_{t \to \infty} \gamma^*(t) \leq 2M\).

It remains to show that the limit above cannot be strictly less than \(2M\). To this end we consider a radially outgoing null geodesic as long as \(\gamma(t) < \sigma(t) = 2M + \alpha e^{-\beta t}\). Then

\[
\frac{d\gamma}{ds} = e^{(\mu - \lambda)(s, \gamma(s))} \leq e^{\mu(s, \sigma(s))} = \left( \frac{\sigma(s) - 2M}{\sigma(s)} \right)^{1/2} \leq Ce^{-\beta s/2},
\]

and hence for any \(0 \leq t_0 \leq t\) and as long as \(\gamma(t) < \sigma(t)\),

\[
\gamma(t) \leq \gamma(t_0) + Ce^{-\beta t_0/2},
\]

where the constant \(C > 0\) again depends only on the initial data set. Now assume that \(R^* := \lim_{t \to \infty} \gamma^*(t) < 2M\), choose \(t_0 > 0\) such that \(R^* + Ce^{-\beta t_0/2} < 2M\), and consider the radially outgoing null geodesic \(\gamma^{**}\) with \(\gamma^{**}(t_0) = R^*\). Then by construction, \(\gamma^{**}(t) < 2M < \sigma(t)\) for all \(t \geq t_0\), and since \(\gamma^{**}(t_0) = R^* > \gamma^*(t_0)\) it follows that \(\gamma^{**}(0) > \gamma^*(0) = r^*\). Hence \(\gamma^{**}\) is a radially outgoing null geodesic which at time \(t = 0\) starts to the right of \(r^*\) and does not escape to \(r = \infty\). This is in contradiction to the definition of \(r^*\).

We conclude this section by proving the remark after Theorem 3.1. Under our general matter conditions the matter is ingoing in the region \(D\), in particular, the matter is for all time restricted to the region where \(r \leq R_1\).
Hence for $r \geq R_1$ the metric is again equal to the Schwarzschild one with mass $M$, and if we replace $2M$ by $R_1$ in the above argument for part (c) we obtain the assertions on $\gamma^s$ in the general matter context. As to the divergence of $\mu$ we observe that

$$\frac{d}{ds}\hat{\mu}(s, \gamma^-(s)) = \hat{\mu}_t(s, \gamma^-(s)) + \hat{\mu}_r(s, \gamma^-(s)) \frac{d\gamma^-}{ds}(s) \leq 0$$

so that the limit $\hat{\mu}_\infty := \lim_{s \to \infty} \hat{\mu}(s, \gamma^-(s))$ exists. The fact that $\gamma^-(s) > 0$ is decreasing with

$$\left| \frac{d\gamma^-}{ds}(s) \right| = e^{(\mu-\lambda)(s,\gamma^-)}(s) \geq e^{2\hat{\mu}(s,\gamma^-)(s)} \geq e^{2\hat{\mu}_\infty},$$

implies that $\hat{\mu}_\infty = -\infty$. Since $\mu \leq \hat{\mu}$ we conclude that

$$\lim_{s \to \infty} \mu(s, \gamma^-(s)) = -\infty,$$

from which the assertion follows by the monotonicity of $\mu$ with respect to $r$.
